

# MODELLING SUPERNOVAE IN THEIR NEBULAR PHASE

Anders Jerkstrand

# History of late-time SN observations

- From  $\sim 100 - 1000\text{d}$  post explosion.
- Powering by  $^{56}\text{Ni} \rightarrow ^{56}\text{Co} \rightarrow ^{56}\text{Fe}$ .

Filippenko+1986: First good-quality nebular spectrum of a SN.

# Nebular phase analysis - pros and cons

Photospheric phase → Nebular phase → Remnant phase

## Pros:

- Probes the core of the exploded star - SN nucleosynthesis can be inferred.

# Nebular phase analysis - pros and cons

Photospheric phase → Nebular phase → Remnant phase

## Pros:

- Probes the core of the exploded star - SN nucleosynthesis can be inferred.
- Line profiles diagnose the 3D structure and link to explosion physics.

# Nebular phase analysis - pros and cons

Photospheric phase → Nebular phase → Remnant phase

## Pros:

- Probes the core of the exploded star - SN nucleosynthesis can be inferred.
- Line profiles diagnose the 3D structure and link to explosion physics.
- Less line blending than photospheric phase (lower  $\nu$  and  $T$  for emitting gas).

# Nebular phase analysis - pros and cons

Photospheric phase → Nebular phase → Remnant phase

## Pros:

- Probes the core of the exploded star - SN nucleosynthesis can be inferred.
- Line profiles diagnose the 3D structure and link to explosion physics.
- Less line blending than photospheric phase (lower  $v$  and  $T$  for emitting gas).
- Limited radiative transfer effects → relatively “clean view”.

# Nebular phase analysis - pros and cons

Photospheric phase → Nebular phase → Remnant phase

## Pros:

- Probes the core of the exploded star - SN nucleosynthesis can be inferred.
- Line profiles diagnose the 3D structure and link to explosion physics.
- Less line blending than photospheric phase (lower  $\nu$  and  $T$  for emitting gas).
- Limited radiative transfer effects → relatively “clean view”.

## Cons:

- Complex (mostly NLTE) modelling, and associated challenge in getting physical conditions right.

# Nebular phase analysis - pros and cons

Photospheric phase → Nebular phase → Remnant phase

## Pros:

- Probes the core of the exploded star - SN nucleosynthesis can be inferred.
- Line profiles diagnose the 3D structure and link to explosion physics.
- Less line blending than photospheric phase (lower  $\nu$  and  $T$  for emitting gas).
- Limited radiative transfer effects → relatively “clean view”.

## Cons:

- Complex (mostly NLTE) modelling, and associated challenge in getting physical conditions right.
- Complex mixing in the explosion (macroscopic, maybe some microscopic). Most modelling so far limited to 1D with artificial mixing and can only partly account for this.

# Nebular phase analysis - pros and cons

Photospheric phase → Nebular phase → Remnant phase

## Pros:

- Probes the core of the exploded star - SN nucleosynthesis can be inferred.
- Line profiles diagnose the 3D structure and link to explosion physics.
- Less line blending than photospheric phase (lower  $\nu$  and  $T$  for emitting gas).
- Limited radiative transfer effects → relatively “clean view”.

## Cons:

- Complex (mostly NLTE) modelling, and associated challenge in getting physical conditions right.
- Complex mixing in the explosion (macroscopic, maybe some microscopic). Most modelling so far limited to 1D with artificial mixing and can only partly account for this.
- Illumination bias: We see mainly what is illuminated by the gamma rays (but this problem is worse in remnants, illuminated by X-rays).

# Nebular phase analysis - pros and cons

Photospheric phase → Nebular phase → Remnant phase

## Pros:

- Probes the core of the exploded star - SN nucleosynthesis can be inferred.
- Line profiles diagnose the 3D structure and link to explosion physics.
- Less line blending than photospheric phase (lower  $\nu$  and  $T$  for emitting gas).
- Limited radiative transfer effects → relatively “clean view”.

## Cons:

- Complex (mostly NLTE) modelling, and associated challenge in getting physical conditions right.
- Complex mixing in the explosion (macroscopic, maybe some microscopic). Most modelling so far limited to 1D with artificial mixing and can only partly account for this.
- Illumination bias: We see mainly what is illuminated by the gamma rays (but this problem is worse in remnants, illuminated by X-rays).
- SNe rapidly dim → limited S/N of observed spectra.

# Results examples

1) Explosive nucleosynthesis

2) Hydrostatic nucleosynthesis

3) Hydrodynamics of expansion

# 1) Explosive nucleosynthesis: Stable nickel production

Jerkstrand+2015

- The **Ni/Fe ratio** ( $=^{58-60}\text{Ni}/^{56}\text{Ni}$  at explosion) can be quite **robustly** inferred from  $[\text{Ni II}] 7378 / [\text{Fe II}] 7155$ . Also  $[\text{Ni II}] 1.9 \mu\text{m}$  useful.

# 1) Explosive nucleosynthesis: Stable nickel production

Jerkstrand+2015

	SN	Ni/Fe ( $\times$ solar)	Reference
<b>Solar</b>	1987A	0.5 – 1.5	Wooden+1993, AJ+2015
	2004et	$\sim 1$	Jerkstrand+2012
	2012A	$\sim 0.5$	Jerkstrand+2015
	2012aw	$\sim 1.5$	Jerkstrand+2015
<b>Super-solar</b>	2006aj	2 – 5	Maeda+2007, Mazzali+2007
	2012ec	2.2 – 4.6	Jerkstrand+2015
<b>Extreme</b>	Crab	60 – 75	Macalpine+1989, 2007

- CCSNe make solar or somewhat supersolar Ni/Fe.
- This constrains  $Y_e$  of the layer experiencing explosive oxygen burning (Jerkstrand+2016c).
- We do not see the high  $^{58-60}\text{Ni}$  production expected in ECSNe in any low-velocity SNe (Jerkstrand+2018).

## 2) Hydrostatic nucleosynthesis : Oxygen

Jerkstrand+2012,2014,2015

## 2) Hydrostatic nucleosynthesis : Oxygen

Jerkstrand+2012,2014,2015

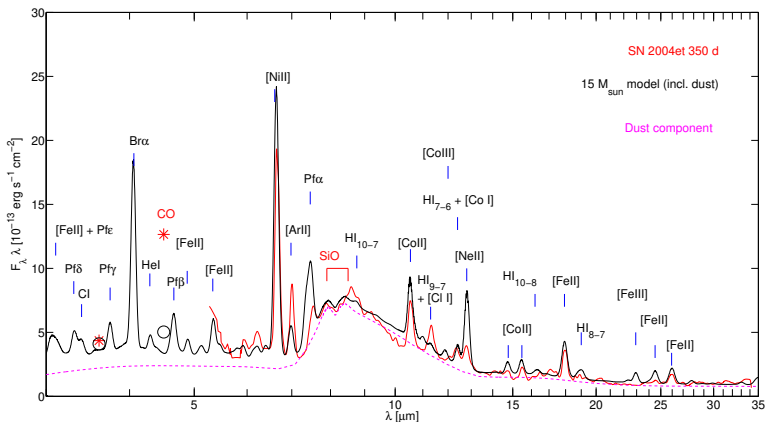

- No sign of stars with He cores  $\gtrsim 6 - 7 M_{\odot}$  exploding as Type IIP, IIb, or Ib SNe (consistent with latest hydromodelling, Melina's talk).

# 3) Hydrodynamics

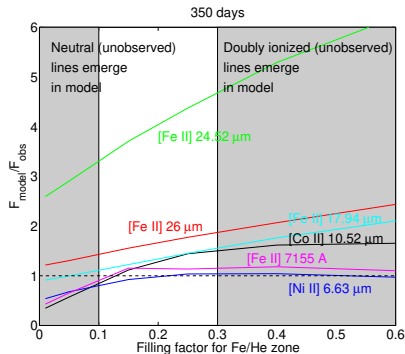

Jerkstrand+2012

- The MIR lines are optically thick, in LTE, and have  $E \ll kT \rightarrow$  (at  $\sim 1y$ ) **robust to infer volume of emission.**

# 3) Hydrodynamics

Jerkstrand+2012

- We can use MIR lines to determine the  $^{56}\text{Ni}$  bubble expansion. SN 1987A and SN 2004et both give volume filling factor  $f \gtrsim 0.2$ .

# 3)Hydrodynamics

## Direct comparison to hydromodels (Gabler+2021):

**Table 4.** Characteristics of the clumps of NiCoFeX after  $t \sim 1$  yr for models B15<sub>0</sub>, B15, B15<sub>X</sub>, N20, L15, and W15, respectively. In the different columns, we give the model name, the fraction of mass of the clumps compared to the total mass of NiCoFeX,  $F_\rho$ , the threshold density above which we define the clumps, the number of clumps, the number of clumps with NiCoFeX mass larger than  $10^{-6} M_\odot$ , the volume of the clumps compared to the volumes inside a sphere with the radius where the mean velocities of the material are  $\bar{v}_{1500} = 1500 \text{ km s}^{-1}$ ,  $\bar{v}_{2500} = 2500 \text{ km s}^{-1}$ , and  $v_{\text{fastest}}^{\text{NiCoFeX}}$ , and finally the surface area in the  $x-z$  plane covered by the NiCoFeX clumps compared to a square with side length of twice the radius where the ejecta move with  $\bar{v}_{1500}$ ,  $\bar{v}_{2500}$ , and  $v_{\text{fastest}}^{\text{NiCoFeX}}$ , respectively.

Model	$F_\rho$	$\rho_{\text{NiCoFeX}}^{\text{min}}$ ( $\text{g cm}^{-3}$ )	Number of clumps	Clumps with $M > 10^{-6} M_\odot$	$V_{\text{NiCoFeX}}^{1500}$	$V_{\text{NiCoFeX}}^{2500}$	$V_{\text{NiCoFeX}}^{\text{fastest}}$	$A_{\text{NiCoFeX}}^{1500}$	$A_{\text{NiCoFeX}}^{2500}$	$A_{\text{NiCoFeX}}^{\text{fastest}}$

Moderate diagnostic potential

Challenging to diagnose

## 3D effects

### Line luminosities:

- Distribution relative to the  $^{56}\text{Ni}$   
→ **illumination**.
- Variation in density →  
**ionization balance**.

### Line profiles:

- Test the **bulk velocities** and  
**degree of asymmetry**.
- Fine-structure → **clumping diagnostic**.

- \* periodic plot: markera in olika förbränningsprocesser
- \* 87A : starta med quasi-bol LC
- \* ref ono arbete etc.
- \* nämn sofies arbete..ta med mol och stoft i "40 yrs of progress".
- \* förklara utmaningar med 3D modelleringen
- \* tiden

# How SUMO consider multi-D effects (until now)

Representation in SUMO : **virtual blobs**  
of different composition.  
(Jerkstrand+2011)

Let blob type  $i$  be characterised by number of blobs  $N_i$  and filling factor  $f_i$ . The blob radius is then found from  $V_{\text{exp}} f_i = N_i \frac{4\pi}{3} R_i^3$  ( $V_{\text{exp}}$  known from line widths). Upon exiting one blob, probability of entering type  $i$  is proportional to its surface area, or

$$p_i = \frac{N_i R_i^2}{\sum N R^2}$$

## 3D hydrosimulations to late times

- Neutrino-driven 3D models evolved to late (=homologous) times have been produced by the Garching group [Wongwathanarat+2013,2015,2017](#), [Gabler+2021 MNRAS](#), [Stockinger+2020](#), [ApJ](#)

N20-4-cw

[Wongwathanarat+2015](#)

- Opportunity to put explosion models to the test
  - Fastest  $^{56}\text{Ni}$ ?
  - Bulk velocity of  $^{56}\text{Ni}$ ?
  - Degree of asymmetry?
  - Composition of Si-burn ashes?

[Wongwathanarat+2017](#)

# 3D modelling: radiative transfer method Jerkstrand+2020

- **Monte Carlo transport in spherical coordinate system**
  - Avoid remapping.
  - Avoid expensive small-cell transport in outer regions, while resolving the small-scale structure in the metal core.
  - More expensive geometry calculations to zone boundaries. Tests show factor few penalty but can be offset by more efficient gridding.

## 3D hydrodynamic model set explored

$M_{ZAMS} = 15 - 20 M_{\odot}$  progenitors exploded with  $\sim 1.5$  Bethe.

Model	Prog.	$E$ ( $10^{51}$ erg)	$M_{ejecta}$ ( $M_{\odot}$ )	$^{56}\text{Ni}$ bulk speed (km/s)	$^{56}\text{Ni}$ asymmetry (km/s)
B15	BSG	1.4	14	1130	145
L15	RSG	1.7	14	1160	398
M15	RSG	1.4	19	1490	473
W15	RSG	1.5	14	1170	517

$$\sum_{cells} |v| \Delta m_{56\text{Ni}} / M_{56\text{Ni}}$$

Imprint on **line widths**

$$= p_{56\text{Ni}} / M_{56\text{Ni}}$$

Imprint on **line asymmetries**

## Example gamma lines (model L15)

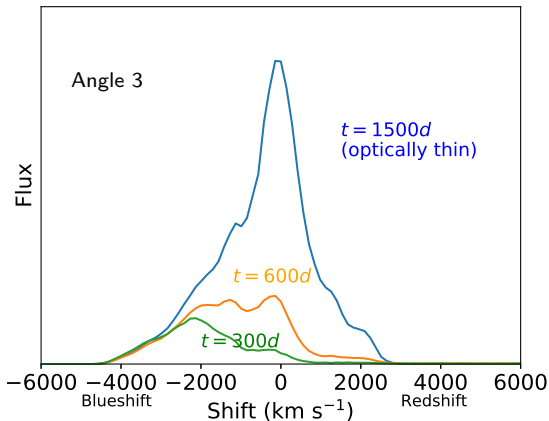

- Lines can have multiple peaks and are generally not “Gaussian”.
- Compton scattering eats away preferentially the red side of the line for several years.

## Example gamma lines (model L15)

- Lines can have multiple peaks and are generally not “Gaussian”.
- Compton scattering eats away preferentially the red side of the line for several years.

## Example gamma lines (model L15)

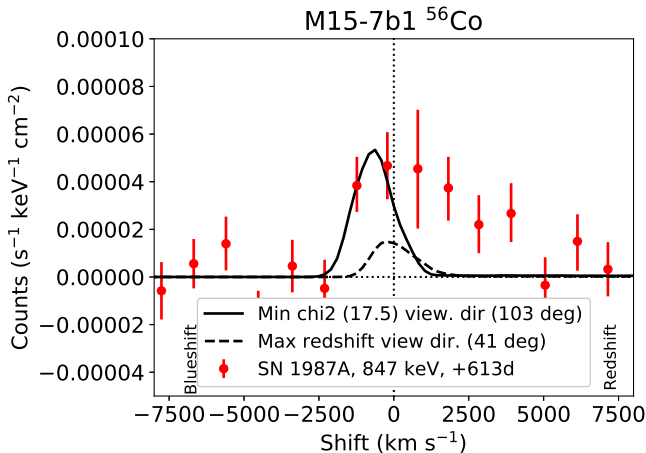

- Lines can have multiple peaks and are generally not “Gaussian”.
- Compton scattering eats away preferentially the red side of the line for several years.

# SN 1987A : $^{56}\text{Co}$ decay lines show redshifts from $\sim 400\text{d}$

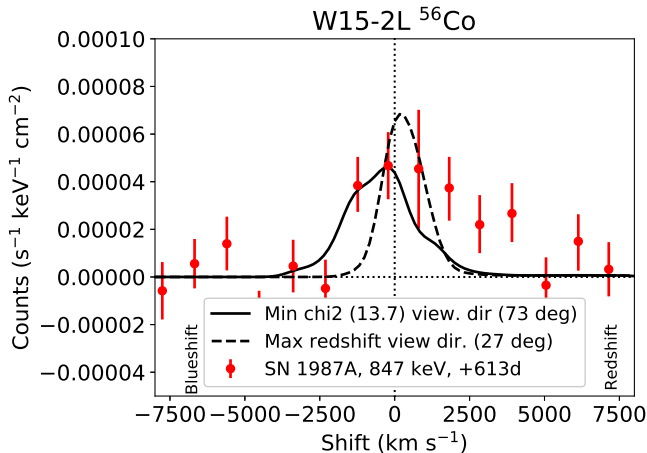

- Models struggle to reproduce emission from receding ejecta with radial velocities up to  $\sim 5000 \text{ km s}^{-1}$  observed (models reach max  $\sim 3000 \text{ km s}^{-1}$ ).

# SN 1987A : $^{56}\text{Co}$ decay lines show redshifts from $\sim 400\text{d}$

- Models struggle to reproduce emission from receding ejecta with radial velocities up to  $\sim 5000 \text{ km s}^{-1}$  observed (models reach max  $\sim 3000 \text{ km s}^{-1}$ ).

# SN 1987A : $^{56}\text{Co}$ decay lines show redshifts from $\sim 400\text{d}$

- Models struggle to reproduce emission from receding ejecta with radial velocities up to  $\sim 5000 \text{ km s}^{-1}$  observed (models reach max  $\sim 3000 \text{ km s}^{-1}$ ).

# SN 1987A : $^{56}\text{Co}$ decay lines show redshifts from $\sim 400\text{d}$

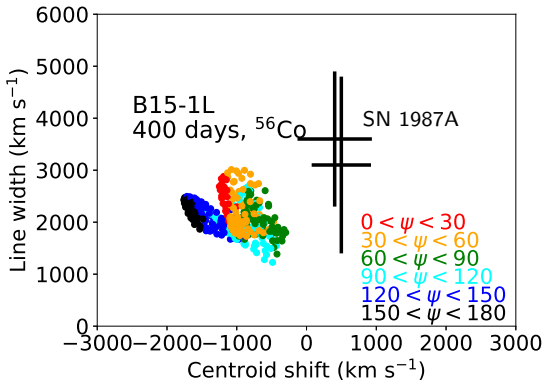

- Models struggle to reproduce emission from receding ejecta with radial velocities up to  $\sim 5000 \text{ km s}^{-1}$  observed (models reach max  $\sim 3000 \text{ km s}^{-1}$ ).

## Viewing angle variations

Define **shift** and **width** of line:

$$V_{shift} = \frac{\int C_E V(E) dE}{\int C_E dE}$$

$$V_{width} = \frac{\int (V(E) - V_{shift})^2 C_E dE}{\int C_E dE}$$

- Shift and width can vary with several 1000 km/s depending on viewing angle.

## Viewing angle variations

Define **shift** and **width** of line:

$$V_{shift} = \frac{\int C_E V(E) dE}{\int C_E dE}$$

$$V_{width} = \frac{\int (V(E) - V_{shift})^2 C_E dE}{\int C_E dE}$$

- Shift and width can vary with several 1000 km/s depending on viewing angle.

# Infrared iron lines in SN 1987

- Observed NIR lines of Fe/Co/Ni also show redshifts.
- Compared to decay line analysis: **better data** and **optically thin**, but **more uncertainty for the emissivity** (here :  $j = d_\gamma \times x_{Fe}$ ).
- Only one model (L15) gives enough width and asymmetry of the IR lines.

## Summary, comparison of current 3D models to SN 1987A

SN 1987A is more extreme in its observed properties of the  $^{56}\text{Ni}$  asymmetry and bulk speed than any of the current models.

But - the best models, at the most favorable viewing angles (NS approaching us) are not too far off maybe  $\sim 25\%$  too slow  $^{56}\text{Ni}$ .

Larsson+2016

# Towards 3D models for optical and IR spectra

## Next steps:

- Solve for NLTE gas state in each cell. (van Baal, step 1)
- Couple in radiation field. (van Baal, step 2)
- The chemistry. (Cherchneff, Sarangi, Liljegren groundworks)

## Discussion points:

- Nebular spectra are sensitive to microscopic composition and clumpiness : to what extent are current Eulerian hydromodels predicting these properties?
- Neutrino-driven models seem quite close to matching SN 1987A : but not quite. What's missing?
- Can we come up with a way to overview and track how each 3D model compares with observations with respect to different observables?

# Chemistry

S. Liljegren et al.: The molecular chemistry of Type Ibc supernovae

**Fig. 8.** Model spectra in the MIR, where each line is the spectra at different times in days indicated by the right label, for the standard model. The fundamental ( $\text{d}\nu = 1$ ) and first overtone ( $\text{d}\nu = 2$ ) molecular bands are indicated. Unblended molecular emission has a light gray background, blends from two bands mid-gray, and blends from three bands dark gray. The flux here is on a log-scale.
